Accident prevention in the Barents Sea

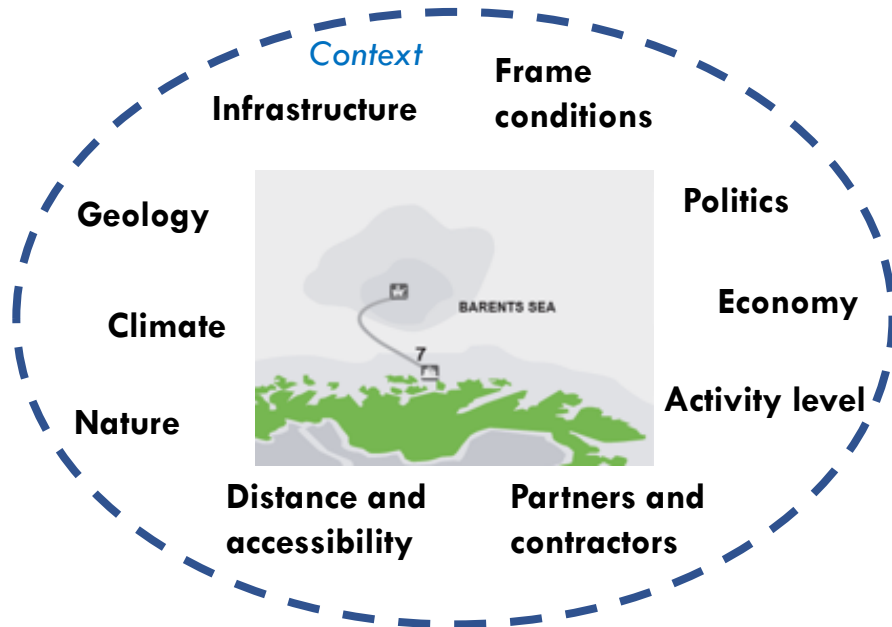

A safety authority perspective on blowout risk

Lin Silje Nilsen, Senior engineer
Ingrid Årstad, Principal engineer
Petroleum Safety Authority

Accident prevention in the Barents sea

Priority – enable prevention of **major accidents**

PSA needs to

- **understand** petroleum activities and its challenges in **context**.
- to **mobilise** and **intervene** proactively when required.

It requires

- **continuous** attention
- **information** and **knowledge**
- **uncertainty** awareness

Assessment of blowout risk

Project background – why and why now?

Ongoing revision of “Forvaltningsplan for Barentshavet”

We need to describe **changes**, how they may **influence** accident risk, and what **needs attention** to prevent accidents.

Deepwater Horizon follow-up

Report to the President (2011) points out improvement in authority risk assessments as crucial to prevent accidents

CSB-report (2016) points at attributes of an effective regulatory model

History of method development

Assessment of blowout risk

What may affect prevention and killing of a blowout?

| Title | Reference | Initiator | Summary |
|-----------------------------|--------------------------|-----------|---|
| HSE in petroleum activities | ASD, 2017 | ASD | General description of conditions related to activity and industry. No particular Barents Sea information. |
| Norwegian climate 2100 | Hansen-Bauer et al, 2015 | MDir | Description of climate change in...sea areas throughout the 21th century...atmospheric climate, hydrology, permafrost, land slides and sea climate. |

Method attributes

Knowledge basis

- collect, appraise and connect information
- independence (selection)
- transparency

Workshops

- appraise knowledge basis and existing understanding
- authority perspective
- address uncertainty

Assessment of blowout risk

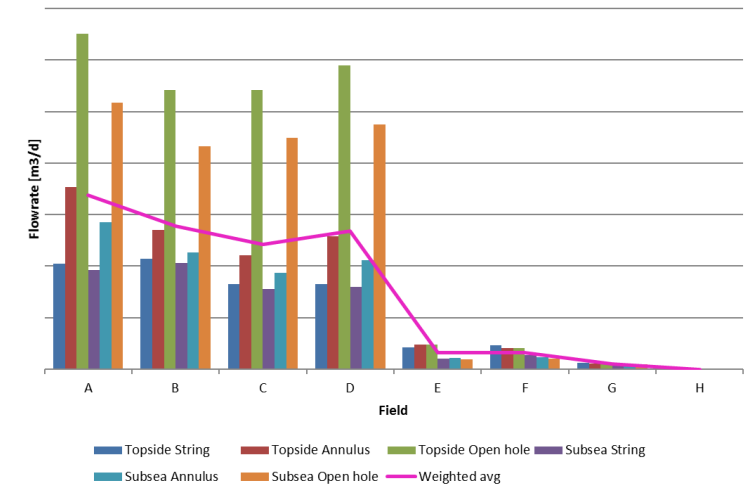

Uncertainty about accident scenarios

- Is existing regulation sufficient to address Barents sea accident scenarios?

Location – where?
Geology, reservoirs
(NPD)

What kind of wells?
Well design, geometry
(PSA)

Blowout model
Combining uncertainties
(IRIS)

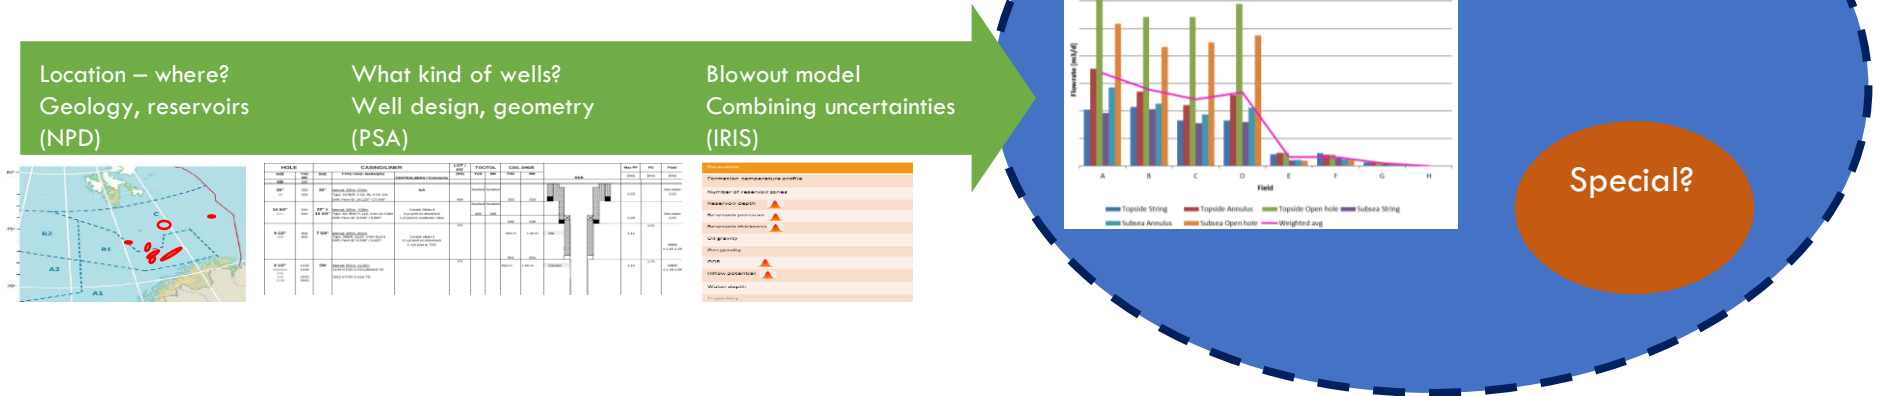

| HOLE | CASING/LINER | | | | LOT / FIT (SG) | TOCTOL | | CSG. SHOE | | RKB | Max PP (SG) | FG (SG) | Field (SG) |

Assessment of blowout risk

Results of this project so far

- Our picture of accident scenarios is well founded and rational.
- Existing regulation is not challenged by the blowout scenarios.

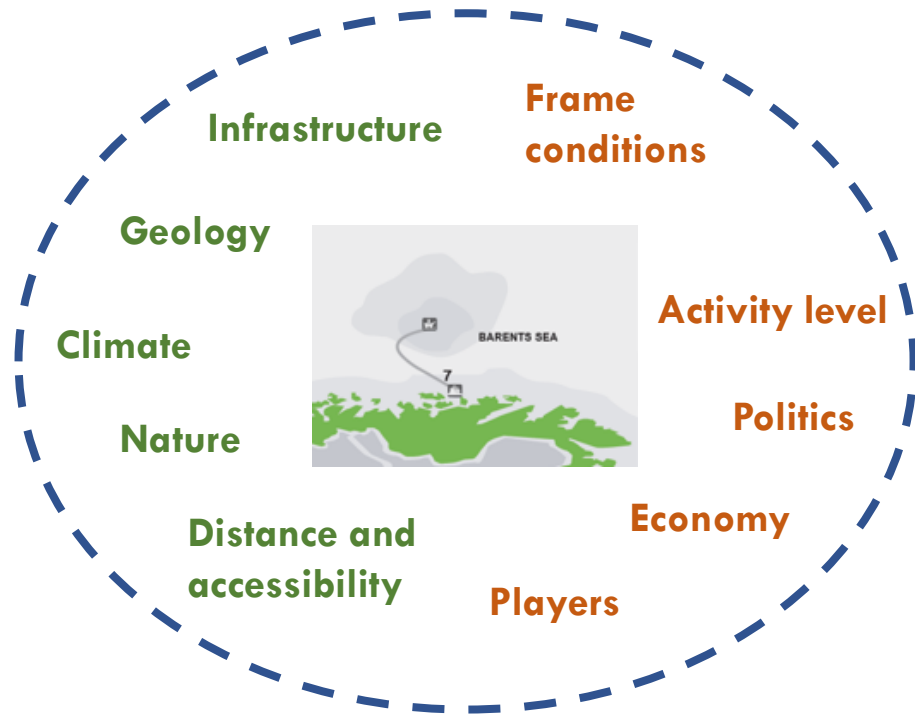

Assessment of blowout risk

What are adequate conditions for low blowout probability in the Barents sea?

Conditions for low blowout risk

Conditions that **cannot** be influenced

Area characteristics and **industry context** may have consequences for technical and operational conditions.

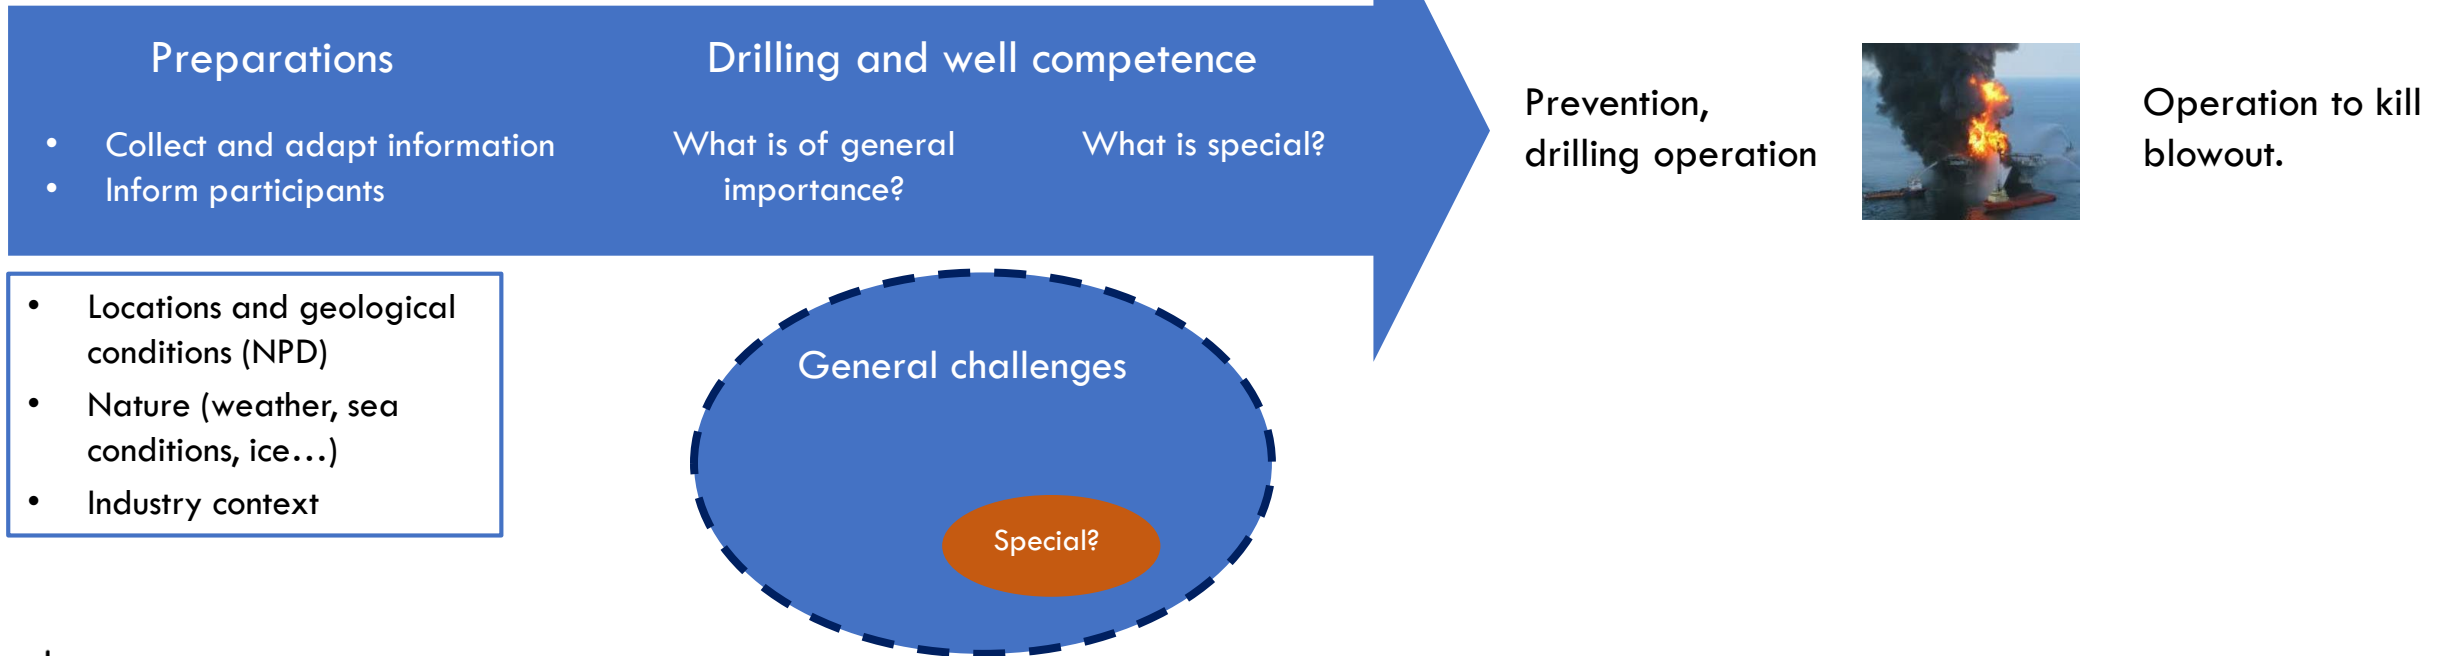

This may alter ability to prevent and stop an accident.

Conditions for low blowout risk

Process to qualify uncertainty

What can influence risk?

What is influenced?

Conditions for low blowout risk

Conditions that can be influenced

Accident risk is influenced by

- technology
- risk management
- frame conditions

Acquire, appraise and connect information

Conditions for low blowout risk

Process to qualify uncertainty

What can influence risk?

Experience from operations, supervisory activities, RNNP, standardisation work, investigations, research and development...

Adapt information

NCS experience

Barents sea experience

Company risk management;

- barrier management
- maintenance management
- adaptations to changes, new areas...
- use of new technology and knowledge

What is influenced?

Prevention,
drilling operation

Operation to kill
blowout.

Conclusion

Providing adequate conditions for low blowout risk

Method development

Qualifies knowledge basis for the safety authority

- updated and relevant
- independent
- transparent

Provides information and facilitate cooperation
(governmental agencies and industry)

Enables the safety authority to

- **understand** petroleum activities and its challenges in **context**
- **mobilise** companies adequately and
- **intervene** proactively when required (regulatory controls)

Attributes of an Effective Regulatory Model

...Those attributes related to the Macondo incident causal factors include [amongst others]:

- Regulator Adaptability
- Regulatory Assessment and Verification
- Regulator Transparency
- Independent, Qualified, and Adequately Funded Regulator

(CSB 2016, Vol. 4)
